## Abstract

We measure the branching fractions for the decays  $\bar{B}^0 \rightarrow D^{*+}e^{-}\bar{\nu}_e$  and  $\bar{B}^0 \rightarrow D^{*+}\mu^{-}\bar{\nu}_\mu$  using  $8.70 \pm 0.09 \text{ fb}^{-1}$  of data collected by the Belle II experiment at the SuperKEKB asymmetric-energy  $e^+e^-$  collider. Candidate signal decays are reconstructed with the subsequent decays  $D^{*+} \rightarrow D^0\pi^+$  and  $D^0 \rightarrow K^-\pi^+$ . We obtain the results  $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+}e^{-}\bar{\nu}_e) = (4.42 \pm 0.14(\text{stat}) \pm 0.33(\text{syst}))\%$  and  $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+}\mu^{-}\bar{\nu}_\mu) = (4.70 \pm 0.13(\text{stat}) \pm 0.35(\text{syst}))\%$ , in agreement with the world averages. The measurements serve to validate the full chain of detector operation and calibration, data collection and processing, and production of physics results in the case of semileptonic  $B$ -meson decays.

## 1. INTRODUCTION

The decays  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell$  (where  $\ell = e$  or  $\mu$ ) are important for measuring the magnitude of the Cabibbo-Kobayashi-Maskawa matrix element  $|V_{cb}|$  and for understanding the hadronic dynamics of  $B$  decays. They also constitute a source of background for charmless semileptonic decays and for the study of  $\bar{B}^0 \rightarrow D^{(*)+}\tau^-\bar{\nu}_\tau$ . All this motivates precise measurements of their branching fractions and kinematic distributions.

The most precise measurements of  $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell)$  were obtained by the *BABAR* [1] and Belle [2] collaborations with data sets recorded a decade ago. Since March 2019, the Belle II experiment has been collecting  $e^+e^-$  collision data with the full detector. The integrated luminosity is still much smaller than those of the aforementioned experiments. However, this measurement of  $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell)$  serves to validate the full analysis chain, from detector operation and calibration, through data collection and processing, to production of physics results, including systematic uncertainties.

## 2. THE BELLE II DETECTOR AND DATA SAMPLE

The Belle II detector [3, 4] operates at the SuperKEKB asymmetric-energy electron-positron collider [5], located at the KEK laboratory in Tsukuba, Japan. The detector consists of several nested detector subsystems arranged around the beam pipe in a cylindrical geometry.

The innermost subsystem is the vertex detector, which includes two layers of silicon pixel detectors and four outer layers of silicon strip detectors. Currently, the second pixel layer is installed in only a small part of the solid angle, while the remaining vertex detector layers are fully installed. Most of the tracking volume consists of a helium and ethane-based small-cell drift chamber.

Outside the drift chamber, a Cherenkov-light imaging and time-of-propagation detector provides charged-particle identification in the barrel region. In the forward endcap, this function is provided by a proximity-focusing, ring-imaging Cherenkov detector with an aerogel radiator. Further out is an electromagnetic calorimeter, consisting of a barrel and two endcap sections made of CsI(Tl) crystals. A uniform 1.5 T magnetic field is provided by a superconducting solenoid situated outside the calorimeter. Multiple layers of scintillators and resistive plate chambers, located between the magnetic flux-return iron plates, constitute the  $K_L$  and muon identification system.

The data used in this analysis were collected at a center-of-mass (CM) energy of 10.58 GeV, corresponding to the mass of the  $\Upsilon(4S)$  resonance. The energies of the electron and positron beams are 7 GeV and 4 GeV, respectively, resulting in a boost of  $\beta\gamma = 0.28$  of the CM frame relative to the lab frame. The integrated luminosity of the data is  $8.70 \pm 0.09 \text{ fb}^{-1}$ .

Simulated Monte Carlo (MC) samples of signal events containing  $10^5$  events for each of  $\bar{B}^0 \rightarrow D^{*+}e^-\bar{\nu}_e$  and  $\bar{B}^0 \rightarrow D^{*+}\mu^-\bar{\nu}_\mu$ , with the subsequent decays  $D^{*+} \rightarrow D^0(\rightarrow K^-\pi^+)\pi^+$ , are used to obtain the reconstruction efficiencies and signal kinematic distributions. These events were generated with EvtGen [6]. Samples of background events are used to obtain

kinematic distributions of the background. These include a sample of  $e^+e^- \rightarrow B\bar{B}$  with generic  $B$ -meson decays, generated with EvtGen, and corresponding to an integrated luminosity of  $100 \text{ fb}^{-1}$ . A  $100 \text{ fb}^{-1}$  sample of continuum  $e^+e^- \rightarrow q\bar{q}$  ( $q = u, d, s, c$ ) is simulated with KKMC [7] interfaced with PYTHIA [8]. All data were analyzed (and, for MC events, generated and simulated) in the basf2 [9] framework.

### 3. EVENT SELECTION

We reconstruct candidate  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell$  decays, with the subsequent decays  $D^{*+} \rightarrow D^0\pi_s^+$ ,  $D^0 \rightarrow K^-\pi^+$ . Here,  $\pi_s$  indicates the soft pion originating from the  $D^{*+}$  decay. Reconstruction of the charge-conjugate decays is implied.

Signal candidate reconstruction begins with the selection of four charged-particle tracks. The distance of closest approach between each track and the interaction point is required to be less than 2 cm along the  $z$  direction (parallel to the beams) and less than 0.5 cm in the transverse  $r - \phi$  plane. All tracks except the  $\pi_s$  candidate must have at least one hit in the drift chamber. The lepton candidate must have a CM frame momentum in the range  $p_\ell^* \in [1.2, 2.4] \text{ GeV}/c$ . It must also satisfy lepton-identification (lepton-ID) criteria based on information from all available detectors. Given the high purity of the decay chain, application of kaon or pion identification criteria is deemed unnecessary and is thus not performed.

A vertex fit is applied to the  $D^0$  candidate, constraining its  $K^-\pi^+$  daughter tracks to originate from a common point. The invariant mass of the  $D^0$  candidate is required to satisfy  $m_{K\pi} \in [1.85, 1.88] \text{ GeV}/c^2$  after the fit. The  $D^{*+} \rightarrow D^0\pi_s^+$  candidate decay is also subjected to a vertex fit, after which the mass difference between the  $D^*$  and  $D^0$  candidates is required to satisfy  $\Delta m \in [0.144, 0.148] \text{ GeV}/c^2$ .

Continuum background is suppressed by requiring the momentum of the  $D^*$  candidate in the CM frame to be less than  $2.5 \text{ GeV}/c$ . Further continuum suppression is achieved by requiring  $R_2 < 0.3$ , where  $R_2$  is the ratio of the second and zeroth Fox-Wolfram moments [10], calculated using all the tracks and photon candidates in the event.

After applying all the selection criteria above, multiple  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell$  candidates are found in about 1% of the events. In these events, we perform a vertex fit for the decay  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell$  and select the candidate with the smallest value of the vertex-fit  $\chi^2$ . The signal efficiency after all selection criteria is  $(19.8 \pm 1.8)\%$  for  $\bar{B}^0 \rightarrow D^{*+}e^-\bar{\nu}_e$  and  $(21.4 \pm 2.2)\%$  for  $\bar{B}^0 \rightarrow D^{*+}\mu^-\bar{\nu}_\mu$ . These values are obtained from signal MC with lepton-ID efficiency corrections obtained from data-MC comparisons of reconstructed  $J/\psi \rightarrow \ell^+\ell^-$  decays. The quoted uncertainties are dominated by the uncertainties on this correction, and also include the much smaller MC-statistical uncertainty.

## 4. SIGNAL YIELD EXTRACTION

For each candidate, we calculate the quantity

$$\cos \theta_{BY} \equiv \frac{2E_B^* E_Y^* - M_B^2 - m_Y^2}{2|p_B^*||p_Y^*|}, \quad (1)$$

where  $E_Y^*$ ,  $|p_Y^*|$ , and  $m_Y$  are the CM energy, momentum, and invariant mass of the  $D^*\ell$  system,  $M_B$  is the nominal  $B$  mass [11], and  $E_B^*$ ,  $|p_B^*|$  are the CM energy and momentum of the  $B$ ; the CM is inferred from the beam four-momenta. For correctly reconstructed  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell$  candidates with perfect detector resolution and correct values of  $E_B^*$  and  $p_B^*$ ,  $\cos \theta_{BY}$  is the cosine of the angle between the momentum of the  $B$  meson and that of the  $D^*\ell$  system in the CM frame. Given the finite beam-energy spread, final-state radiation, and detector resolution, the  $\cos \theta_{BY}$  distribution of signal events extends beyond the range  $[-1, 1]$ . The  $\cos \theta_{BY}$  distributions of data and MC events are shown in Fig. 1.

We obtain the event yields  $N_s$ ,  $N_B$ , and  $N_c$  for signal,  $B\bar{B}$  background, and continuum, respectively, from a binned, extended-maximum-likelihood fit to the  $\cos \theta_{BY}$  distribution of the data. The probability density function (PDF) used in the fit is the sum of the PDFs of these three event categories. These PDFs are obtained from the MC samples, after application of momentum- and polar-angle-dependent corrections to the lepton-identification efficiencies of leptons and hadrons. For leptons, corrections of the order of a few percent are obtained from  $J/\psi \rightarrow \ell^+\ell^-$  ( $\ell = e, \mu$ ) decays. Corrections for hadrons misidentified as leptons, obtained from samples of reconstructed  $D^0 \rightarrow K^-\pi^+$  decays, are of order unity in some regions. Applying these corrections to the PDFs changes the signal yield from the fit by 0.5% for  $\bar{B}^0 \rightarrow D^{*+}e^-\bar{\nu}_e$  and by 0.1% for  $\bar{B}^0 \rightarrow D^{*+}\mu^-\bar{\nu}_\mu$ .

The fit results are shown in Fig. 1 and summarized in Table I.

Event type	$\bar{B}^0 \rightarrow D^{*+}e^-\bar{\nu}_e$ Yield	$\bar{B}^0 \rightarrow D^{*+}\mu^-\bar{\nu}_\mu$ Yield
$N_s$ (Signal)	$2199 \pm 69$	$2525 \pm 68$
$N_{B^0}$ ( $B\bar{B}$ )	$1377 \pm 123$	$1306 \pm 129$
$N_c$ (Continuum)	$369 \pm 106$	$597 \pm 116$

TABLE I. Signal,  $B\bar{B}$ , and continuum event yields obtained from the fits shown in Fig. 1. The uncertainty is statistical.

The branching fraction is obtained from the signal yield via

$$\mathcal{B}(\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}_\ell) = \frac{N_s}{\epsilon \times N_{B^0} \times \mathcal{B}(D^{*+} \rightarrow D^0\pi^+) \times \mathcal{B}(D^0 \rightarrow K^-\pi^+)}, \quad (2)$$

where  $\epsilon$  is the product of the signal reconstruction efficiency and acceptance, and  $N_{B^0}$  is the number of  $B^0$  mesons in the data sample, further discussed in section 5.

## 5. SYSTEMATIC UNCERTAINTIES AND CROSS CHECKS

The relative systematic uncertainties affecting the measurement are listed in Table II. We assume no correlation among the individual sources of uncertainty and sum them in

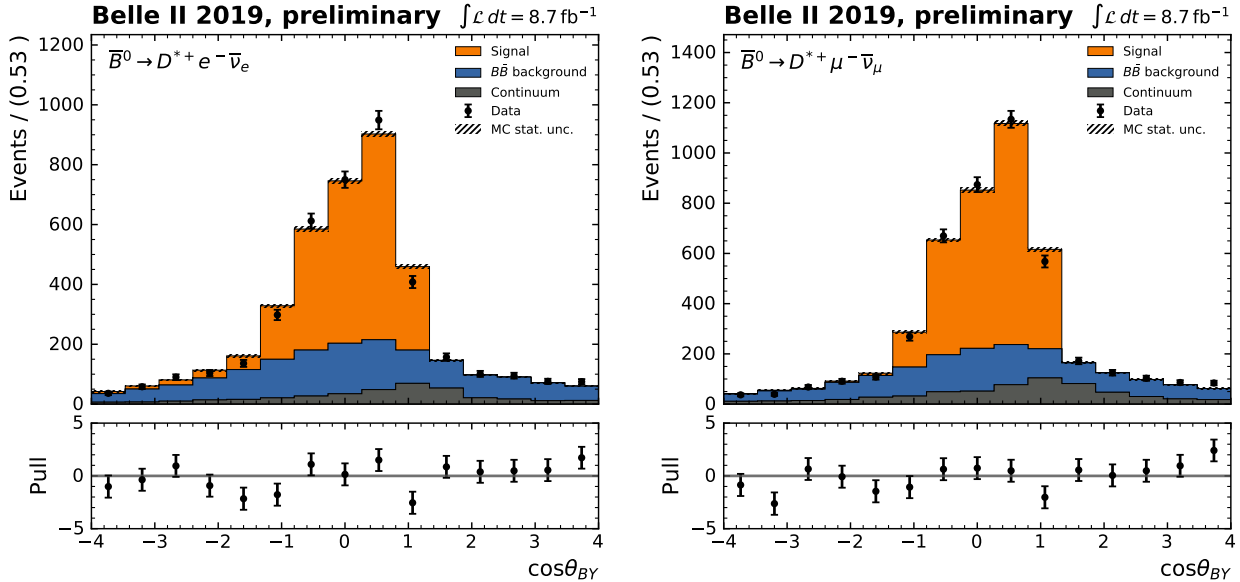

FIG. 1. Post-fit  $\cos\theta_{BY}$  distributions for the selected  $\bar{B}^0 \rightarrow D^{*+}e^{-}\bar{\nu}_e$  (left) and  $\bar{B}^0 \rightarrow D^{*+}\mu^{-}\bar{\nu}_\mu$  (right) candidates (data points), overlaid with the signal,  $B\bar{B}$  background, and continuum PDFs used in the fit as obtained from simulated MC events (histograms). The pull distributions show the difference between the data and total PDF divided by the square root of the number of data events in each bin.

quadrature to obtain the total systematic uncertainty. The methods used for obtaining these uncertainties are described below.

The lepton-identification corrections are measured with statistical uncertainties that arise from the limited size of the control samples, as well as systematic uncertainties. We produce 500 sets of correction values sampled from Gaussian distributions that reflect these uncertainties, accounting for systematic correlations. Each set of corrections is used to produce new MC PDFs that are used to refit the data  $\cos\theta_{BY}$  distribution. The standard deviation of the distribution of the signal yield obtained with the 500 sets is 2 events for both  $\bar{B}^0 \rightarrow D^{*+}e^{-}\bar{\nu}_e$  and  $\bar{B}^0 \rightarrow D^{*+}\mu^{-}\bar{\nu}_\mu$ . This value is thus used as the associated systematic uncertainty on the signal yield. The same procedure is used to calculate the correction on the absolute lepton-identification efficiency affecting the overall signal efficiency.

The impact of the finite sizes of the MC samples on the fit result is evaluated by varying the MC PDFs bin-by-bin according to Poisson distributions, and repeating the fit 500 times. We take the standard deviation of the resulting signal-yield distribution to estimate the systematic uncertainty.

The semileptonic decays  $\bar{B} \rightarrow D^{**}\ell\bar{\nu}$ , where  $D^{**}$  indicates an excited charm meson heavier than the  $D^*$ , have a similar particle content to that of signal decays. As a result, the fit may be biased if the branching fractions of  $\bar{B} \rightarrow D^{**}\ell\bar{\nu}$  are incorrect in the generic MC sample. To estimate the systematic uncertainty, we obtain the  $B\bar{B}$  PDF from the MC after varying the branching fractions for these decays by  $\pm 25\%$ , which is twice the relative uncertainty on  $\mathcal{B}(\bar{B} \rightarrow D^0\pi^+\ell^-\bar{\nu})$ . The resulting change in the signal yield is taken as the systematic

Source	Relative uncertainty (%)	
	$\bar{B}^0 \rightarrow D^{*+} e^- \bar{\nu}_e$	$\bar{B}^0 \rightarrow D^{*+} \mu^- \bar{\nu}_\mu$
Lepton-ID, PDF	0.09	0.08
MC statistics, PDF	0.64	0.55
$\mathcal{B}(\bar{B} \rightarrow D^{**} \ell \bar{\nu})$	0.18	0.08
Efficiency momentum dependence	0.1	0.1
PDF binning	0.5	0.5
Lepton-ID, efficiency	1.8	2.2
MC statistics, efficiency	0.13	0.13
Tracking of $K, \pi, \ell$	2.5	2.5
Tracking of $\pi_s$	6.0	6.0
$N_{B^0}$	2.7	2.7
Charm branching fractions	1.1	1.1
Total	7.40	7.50

TABLE II. Summary of the relative systematic uncertainties for the measurements of  $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell)$ . The first five uncertainties impact the extracted signal yield, while the others impact the other factors of Eq. (2).

uncertainty.

Further Data-MC differences in the reconstruction efficiency as a function of the momenta  $p_\ell$  and  $p_{\pi_s}$  of the lepton and soft-pion may affect the  $\cos\theta_{BY}$  PDFs and hence the signal yield. Figure 2 shows the  $p_\ell$  and  $p_{\pi_s}$  distributions in the CM frame for data and MC, with the corresponding distributions of the pull  $(N_{\text{data}} - N_{\text{MC}})/\sqrt{N_{\text{data}}}$  in each bin. The  $\chi^2$  per degrees of freedom of the pull distributions is  $\chi^2/N_{\text{DOF}} = 1.6$  for Figs. 2a, b, c, and 3.1 for Fig. 2d, where  $N_{\text{DOF}} = 9$ . To test the impact of this relative disagreement on the fit, we reproduce the  $\cos\theta_{BY}$  PDFs after reweighting each MC event so as to obtain  $\chi^2/N_{\text{DOF}} = 1$  in the  $p_{\pi_s}$  and  $p_\ell$  pull distributions. Using these modified PDFs to perform the fit leads to a maximal change in the fit yield of 0.1%, which is taken as a systematic uncertainty.

The systematic uncertainty due to the choice of the number of bins in the PDF is estimated to be 0.5% by varying the number of bins up to 40.

The tracking efficiency uncertainty for the lepton, kaon, and pion is 0.82% per track. This is obtained by comparing  $R_{2/3}$  for  $e^+e^- \rightarrow \tau^+\tau^-$  events in data and MC, where  $R_{2/3}$  is the fraction of 3-prong  $\tau$  decays in which only two hadron tracks are found. The uncertainty on the soft pion tracking efficiency, 6.0%, is calculated as 20% of the inefficiency obtained from MC. The value of 20% is taken from data-MC comparison studies performed with high-momentum tracks.

To obtain the number of  $B^0$  mesons in the sample, we use the relation

$$N_{B^0} = \mathcal{L} \times \sigma(e^+e^- \rightarrow \Upsilon(4S)) \times 2 \times f^{00}. \quad (3)$$

Here  $\mathcal{L}$  denotes the integrated luminosity, measured to be  $8.70 \pm 0.09 \text{ fb}^{-1}$  using  $e^+e^- \rightarrow e^+e^-$  and  $e^+e^- \rightarrow \gamma\gamma$  events [12]. The factor  $f^{00} = 0.487 \pm 0.013$  is the fraction of neutral  $B$

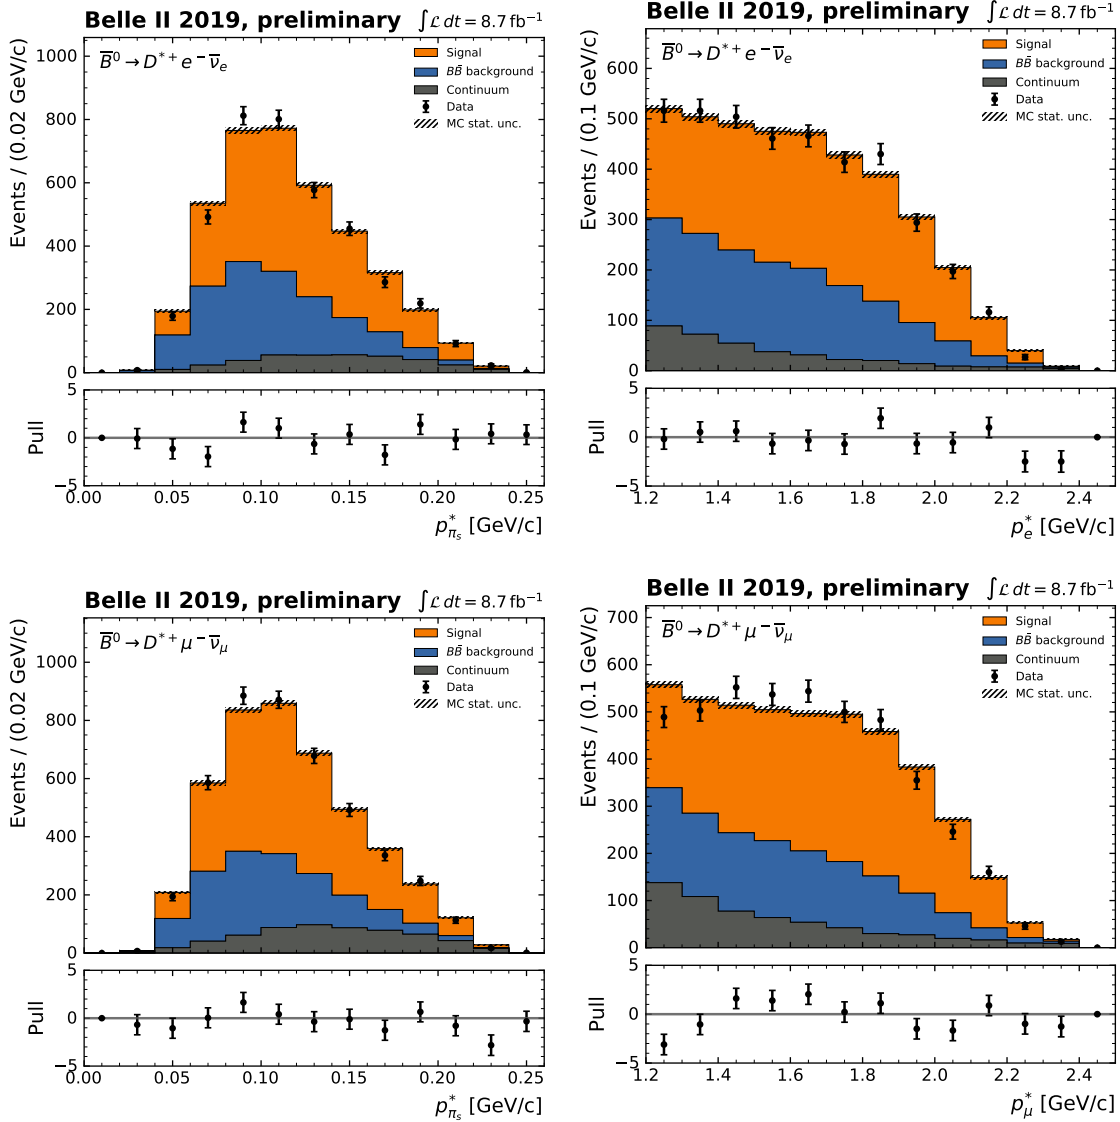

FIG. 2. Distribution of the CM momentum of the slow pion (left plots) and lepton (right plots) for the  $\bar{B}^0 \rightarrow D^{*+} e^- \bar{\nu}_e$  (top plots) and  $\bar{B}^0 \rightarrow D^{*+} \mu^- \bar{\nu}_\mu$  (bottom plots) modes. The data distributions are overlaid with the MC PDFs, scaled according to the fit results.

mesons produced in  $\Upsilon(4S)$  decays [11]. We take the effective cross section  $\sigma(e^+e^- \rightarrow \Upsilon(4S))$  to be  $1.110 \pm 0.008$  nb from measurements of the number of  $B$ -meson pairs produced [13] and of the integrated luminosity [14] at the  $BABAR$  experiment. This assumes that the branching fraction for  $\Upsilon(4S)$  decays to non- $B\bar{B}$  final states is negligible. We assign an additional uncertainty of 2% on this value, to account for the possibility that the average SuperKEKB CM energy is off the  $\Upsilon(4S)$  resonance by up to 1.5 MeV.

Lastly, we account for the impact of the uncertainties in the charm branching fractions,  $\mathcal{B}(D^{*+} \rightarrow D^0 \pi^+) = (67.7 \pm 0.5)\%$  and  $\mathcal{B}(D^0 \rightarrow K^- \pi^+) = (3.950 \pm 0.031)\%$  [11], on the signal branching fraction.

## 6. BRANCHING FRACTION RESULTS AND SUMMARY

From Eq. (2) we measure for the  $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$  branching fractions:

$$\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} e^- \bar{\nu}_e) = (4.42 \pm 0.14(\text{stat}) \pm 0.33(\text{sys}))\%, \quad (4)$$

$$\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \mu^- \bar{\nu}_\mu) = (4.70 \pm 0.13(\text{stat}) \pm 0.35(\text{sys}))\%. \quad (5)$$

Considering the statistical uncertainties only, the branching fractions for the two modes are consistent to within 1.5 standard deviations.

In summary, we measure the branching fractions of the decays  $\bar{B}^0 \rightarrow D^{*+} e^- \bar{\nu}_e$  and  $\bar{B}^0 \rightarrow D^{*+} \mu^- \bar{\nu}_\mu$  using  $8.7 \text{ fb}^{-1}$  of data collected by the Belle II experiment in 2019. The world average value of the branching fraction  $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell) = (5.05 \pm 0.14)\%$  [11] was obtained with a different value of the  $D^0$  branching fraction,  $\mathcal{B}(D^0 \rightarrow K^- \pi^+) = (3.89 \pm 0.04)\%$ . Accounting for this difference, our results are lower than the world average by 1.5 and 0.7 standard deviation for the  $\bar{B}^0 \rightarrow D^{*+} e^- \bar{\nu}_e$  and  $\bar{B}^0 \rightarrow D^{*+} \mu^- \bar{\nu}_\mu$  modes, respectively. While the uncertainties we estimate are significantly larger than those of the world average, this is the first branching-fraction measurement performed with Belle II data, and constitutes a test of the entire data production, processing, and analysis chain.

## 7. ACKNOWLEDGEMENTS

We thank the SuperKEKB group for the excellent operation of the accelerator; the KEK cryogenics group for the efficient operation of the solenoid; and the KEK computer group for on-site computing support. This work was supported by the following funding sources: Science Committee of the Republic of Armenia Grant No. 18T-1C180; Australian Research Council and research grant Nos. DP180102629, DP170102389, DP170102204, DP150103061, FT130100303, and FT130100018; Austrian Federal Ministry of Education, Science and Research, and Austrian Science Fund No. P 31361-N36; Natural Sciences and Engineering Research Council of Canada, Compute Canada and CANARIE; Chinese Academy of Sciences and research grant No. QYZDJ-SSW-SLH011, National Natural Science Foundation of China and research grant Nos. 11521505, 11575017, 11675166, 11761141009, 11705209, and 11975076, LiaoNing Revitalization Talents Program under contract No. XLYC1807135, Shanghai Municipal Science and Technology Committee under contract No. 19ZR1403000, Shanghai Pujiang Program under Grant No. 18PJ1401000, and the CAS Center for Excellence in Particle Physics (CCEPP); the Ministry of Education, Youth and Sports of the Czech Republic under Contract No. LTT17020 and Charles University grants SVV 260448 and GAUK 404316; European Research Council, 7th Framework PIF-GA-2013-622527, Horizon 2020 Marie Skłodowska-Curie grant agreement No. 700525 ‘NIOBE,’ and Horizon 2020 Marie Skłodowska-Curie RISE project JENNIFER grant agreement No. 644294 (European grants); L’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3) du CNRS (France); BMBF, DFG, HGF, MPG and AvH Foundation (Germany); Department of Atomic Energy and Department of Science and Technology (India); Israel Science Foundation grant No. 2476/17 and United States-Israel Binational Science Foundation grant No. 2016113; Istituto Nazionale di Fisica Nucleare and the research grants BELLE2; Japan Society for the Promotion of Science, Grant-in-Aid for Scientific
